The Parapodium: An Orthotic Device for Neuromuscular Disorders

Some of the serious shortcomings of the standard brace for young patients with paralysis of the lower extremities are the lack of adjustability to accommodate growth and contractures, excessive weight, instability, difficulty in locking and unlocking, and the time required for donning and removal. The Parapodium (3) was designed in the effort to introduce a modular system that offers alternatives and resolves some of those difficulties.

The Parapodium facilitates standing without crutches, thus freeing the patient's hands for a wider range of activities. The difference between tripod standing and crutchless standing is a major distinction between our approach to brace design and that of conventional braces.

This orthosis is best suited for patients with severe spina bifida or traumatic paraplegia; however, it also may be prescribed for other neuromuscular disorders in which stability of the brace (permitting standing or swivelling without crutches), lightness of the device, and an upright position are important.

Because of the modular design, growth in a child is easily accommodated. The footplate will accept several sizes of regular boots; there are four sizes of footplates for boots from 5 1/2 in. to 9 1/2 in. long. The height of the Parapodium can be adjusted by replacing the tubular sidebars with a longer piece of tubing, which is cut from standard 1/2-in. or 5/8-in. aluminum tubing, and the back panel is made in two pieces to provide for width adjustment.

The Parapodium is constructed of lightweight, high-strength aluminum (2024T6) throughout. The average weight is between 8% and 14% of the body weight. The weight of a standard brace may be as much as 15% to 22%.

For stability, the footplate, sidebars, and back panel form a continuous rigid loop, cross-braced by a bar at the level of the knee. The shape of the bar virtually eliminates side-to-side movement, thus improving the anterior-posterior and medial-lateral stability of the unit.

The knee pads are shaped from 2-in. Ethafoam (TM) blocks. If contractures occur, they can be accommodated by deepening the knee cutouts in the foam block.

One of the unique features of this orthosis is the means used to lock and unlock the hip and knee joints. A set of folding handles is used to rotate the upright bars and thus rotate the hip and knee joints. For standing, the joint axes are aligned in the A-P direction; when rotated 90 degrees to the M-L position, the joints are free to flex. Also, it should be noted that one of the more difficult tasks a paraplegic has is to extend his extremities fully so that he can lock his braces; the rotating sidebars not only lock the brace, but also extend it the last few degrees.

Since the patient's shoes are not permanently attached to the brace, he is able to put on and remove the brace without wasting time lacing and unlaceing the boot. Also, the boot remains on the patient's foot to
MOTLOCK

protect it from scratches and bruises. In
addition, the time for donning and remov¬
ing the brace has been greatly reduced
because of the simplicity of the locking
method. Our older patients can remove this
brace in 15 to 20 seconds, whereas it could
take from 5 to 20 minutes to remove a stan¬
dard brace. Donning the Parapodium takes
45 to 90 seconds; donning a standard brace
takes 10 to 20 minutes.

A minimum of maintenance is required.
Because of the use of aluminum, the parts
do not need to be plated to prevent corro¬
sion, there are no delays for plating, and
nylon does not need lubrication. No screws
are used in the sidebars, nor leather for
straps.

Because of the modular kit, the device
can be assembled speedily. If no special
modifications of the kit are needed, the
fitting can be completed in two hours. Also,
repairs or growth adjustments can be made
while the patient waits.

Simple, clean lines, with no buckles,
straps, or corsets, have superseded the
cluttered look of the standard braces. The
aluminum is easily cleaned or buffed, and
it may be anodized when the brace is
finished.

The Parapodium is easily aligned. An
alignment block at the bottom of each up¬
right enables the orthotist to align the brace
while it is being worn. The brace can be
aligned for maximum comfort while stand¬
ing or for maximum stability.

CLINICAL CONSIDERATIONS

When the child indicates the desire to
stand up by pulling up on furniture and
other objects, or when he has developed
sufficiently to stand, a bracing program may
commence. (For a presentation on the
orthotics aspects of treating children with
spina bifida, the reader is referred to
"Therapy Treatment Suggestions" by
Elizabeth L. Hamilton, P.T., in 3.)

In some cases, a prebracing device, the
"caster cart" (2,3), or a preliminary brace,
the "standing brace" (2,5), may be used.
At this center, the criteria for considering
the use of the Parapodium are:

1. The patient does not have sufficient
muscle power in his lower extremities and
trunk to ambulate and stand without
criutches.
2. The patient has either gone through
the standing-brace stage or is physically and
mentally ready to go directly into the
Parapodium.
3. The patient is of such size that com¬
fortable sitting can only be accomplished
by flexing the knees and hips.

In addition, the following points should
be checked before a Parapodium is
considered:

1. Upper-extremity coordination and
strength. Can this person use crutches or
walkers effectively for ambulation? If only
standing is required, this point might not
be important.
2. Condition of the feet. Can shoes be
worn? Can the skin, bones, and joints with¬
stand weight-bearing? Custom shoes,
special padding, and plantar-flexion
wedges could be used. A physiotherapy
program can prepare the patient for
weight-bearing.
3. Deformities and contractures. Check
the legs, pelvis, and spine for severe de¬
formities. Orthopedic surgery and physio-
therapy can be of great value. Minor
deformities can be accommodated without
special modifications.
4. Skin condition. Check for sores and
for hypersensitive areas over the chest
(front panel area), sacrum (buttocks sup¬
port), and patellar tendon and knees (knee
pads).
5. Protruding myelomeningocele and
spinal deformities. Can a body jacket sup¬
port the trunk? Is there enough clear area

Fig. 2. The semi-assembled Parapodium kit as it
is supplied by the manufacturer.
over the sacrum for a good buttocks-support panel?

ASSEMBLY AND FITTING

The parts of the Parapodium and the "kit" supplied by the manufacturer are shown in figures 1 and 2.

The tools required to assemble the kit are: a tape measure, knife, hacksaw, file, portable drill with 1/8-in. drill bit, pop-riveter, and a 1/2-in. reamer.

Step 1. Obtain a pair of face-to-toe boots. Check their fit on the patient carefully; it is better that they tend to be loose rather than tight.

Step 2 (fig. 3). Fit the shoes into the footplate. Make sure that the clamps (toe and heel) hook securely over the welt of the shoe and that the spring is taut enough to hold the shoes in place. Sometimes it may be necessary to change the height of the heel-clamp block, toe-clamp post, and the curvature cutouts of the heel and toe clamps.

Figure 4 illustrates the position of the knee pad. Note that the patellar tendon is used in this case and that the block has to be shaped to concentrate pressure on the patellar tendon.

Step 3 (fig. 5). With the shoes on the patient, clamp the lower part of the brace in place. Hold the knees in the desired position (anteroposterior and mediolateral) and mark the cutout for the knee on the foam block.

Step 4 (fig. 6). With the marked knee pad over the patellar tendon, mark the length of the tube shin section.
Step 5 (fig. 7). The knee cutouts are shaped as marked.

Step 6 (fig. 8). Check the fit of the knee cutouts. At this time, only a rough fit is necessary; a final check and smoothing is done later.

Step 7 (fig. 9). Cut off the tube shin sections as marked in step 4. File the end flat and clean out the burr from the inside of the tube.

Step 8 (fig. 10). Clamp the lower section in place and check the fit of the knee cutouts to ensure patellar-tendon pressure-bearing, and also check the length of the shin sections.

**BACK PANEL**

The back panel is effective only in cases of good spine stability, minor deformities, and meningocele protuberance higher than the sacral area. For fitting of more severe cases, see the "Spinal Deformities" section.

The panel should be fitted rather loosely because the width across the greater trochanters increases with weight-bearing (fig. 11).
Step 9 (fig. 12). With the patient on his stomach, and his legs over the edge of the fitting table, place the two halves of the back panel on the patient's back and mark the width. Two pop rivets are used to hold the halves together temporarily; the final adjustments and riveting are made when the patient stands in the brace.

Step 10 (fig. 13). With the patient sitting, check the fit at the greater trochanters, in the sacral area, and the axilla. Sometimes it is necessary to place padding over the sacrum, especially in cases of tenderness, scarring, and bony protuberances. Also, the side supports might have to be lengthened or shortened to be one inch lower than the axilla border.

Figure 14 shows the desired position of the front panel, anterior view, with the center of the panel on the xiphoid process.

Step 11 (fig. 15). Rivet and fasten the Velcro strap. Check the position of the panel, the length of the strap, and the angle of the rotation stops. Sometimes they are pinned incorrectly and have to be repinned. The tubular thigh sections should be lined up parallel.

Step 12 (fig. 16). Place the lower and upper sections of the brace in the correct position and mark the length of the tube thigh section.
Step 13 (fig. 17). Cut off the thigh sections to the length marked; file the ends square and remove the burr.

Step 14. Using Vaseline as a lubricant, insert the tube sections in the knee joint. Note: This should be a sliding fit only; do not force or hammer these parts in or they will be damaged permanently. In some cases, an adjustable reamer is needed to get a good fit. This should be done carefully because a sloppy fit will cause instability of the brace. Do not rivet the lower and upper sections to the knee joint yet, but rather, slide the tubes in place (use Vaseline).

Step 15 (fig. 18). Have the patient sit on a chair, with hips and knees flexed 90 degrees (more than the figure shows). There should be 1/4 in. to 1/2 in. space between the loam cutouts and the front of the knee in this position. The back panel should be touching the sacral area, and the tubes should be fully inserted in their receptacle.

Step 16. Place the patient in his brace on the fitting table. Using the handles to turn the hip joints, and by manually turning the knee joints, lock the brace for standing. Hold the brace parts together at the knee with both hands. With assistance, slowly stand the patient up (fig. 19). Provide plenty of physical and moral support at this time.

Carefully check (a) the position of the back and front panel (the lower edge of the panel at the crease of the buttocks), (b) the width of the back panel (see fig. 11), and (c) the position of the knee pad (see fig. 4).
It is important to ensure that the panel does not rise up significantly in standing as compared to sitting. If that occurs, first check the operation in step 12; if that is satisfactory, then the mounting plates have to be raised the distance of the rise, usually 1 in. to 2 in. Also, be sure that the side of the back panel does not interfere with function of the upper extremity.

After the Parapodium has been fitted, it is assembled permanently and the knee cutouts are smoothed.

(a) The knee bar sleeve is lubricated with Vaseline, and the nylon washer is inserted under it. This washer is needed because it prevents the brace from squeaking.

(b) Insert the knee joints, with the bar and washer, into the shin-tube section, drill a 1/8-in. hole for a pop rivet about 1/2 in. from the top of the tube, and pop-rivet together.

(c) Insert the thigh sections (upper part of the brace) into the knee joints and fold the brace into a sitting position; drill a 1/8-in. hole and pop-rivet the thigh section in place.

(d) Stretch the elastic back strap and fasten with a pop rivet.

(e) Straighten and fold the brace a few times to check for stiffness and joint misalignment.

Step 17 (fig. 20). Put the brace on the patient and check the alignment. Optimal alignment is achieved when the patient (without crutches, hands on sides) can almost balance on a quarter-inch dowel. The footplate is divided into three equal parts, and the dowel is placed at the junction of the front one-third and the back two-thirds.

If adjustment in alignment is needed (fig. 21), it is accomplished by tightening one alignment-block nut and loosening the other. The alignment blocks can be rotated, and inclining the brace with a patient in it should always be done to the cutaway side of the block.

Step 18. Crutchless standing in the assembled brace is now possible, but should not be forced on the patient; it will come with time. From now on, wearing tolerance should be built up gradually and activities increased.
ORTHOTIC CHECK-OUT

A form such as is shown in figure 22 can be used for the orthotic check-out.

Fig. 23. Figure 23 shows a tipping platform that is used for objectively measuring and comparing the stability of lower-extremity orthotics while they are being worn.

Fig. 24. A pressure-sensing device, if used routinely, significantly reduces trouble spots by detecting excessive pressure before it causes breakdown of the desensitized skin.

The Parapodium is aligned properly if the patient can tolerate the same number of degrees to the left as to the right, and about one-third forward as compared to two-thirds backward. In this way, the brace is equally stable towards either side, but it is about 30% easier to fall forward than backward, thus facilitating swing-through gait with the use of crutches.

ADAPTATIONS

LEG-LENGTH DISCREPANCY

Sometimes it is necessary to build up the footplate and to change the height of the toe and heel clamp to accommodate leg shortening. A Plastazote (TM) block equal to the shortening is glued to the base plate. The shoe is placed on it, and the clamps are then modified (fig. 24) to hold the shoes in place.

SIGNIFICANT PLANTAR FLEXION

There are two ways of dealing with this problem. If possible, wedged Plastazote shoe inserts should be fabricated and glued in as insoles. However, if the plantar flexion is too great for insoles, a combination of insole wedge and outside wedge can be used. A wedge of Plastazote, with a proper slope, is glued to the base plate, and the heel clamp is raised by lengthening the heel-clamp post.
KNEE HYPEREXTENSION

If the knee has a tendency to go into hyperextension, a 2-in. webbing with Velcro should be used for control. Velcro hooks are pop-riveted to the front of the knee crossbar, and Velcro pile, with a strap, is placed around the back to the front (fig. 25).

TRUNK HYPEREXTENSION

A 2-in. webbing strap is useful in extending the back panel before locking, and it should be put on routinely. It should be riveted as high as possible to the side supports of the back panel. Also, it prevents the patient from hyperextending his trunk while standing (fig. 27).

HIP AND KNEE INSTABILITY

Some children find it difficult to extend their brace prior to locking. A doubled 1-in. elastic strap is riveted to the most anterior point of the knee bar and the most posterior point of the back panel. The strap runs medially to the sidebars, anterior to the knee joint, and posterior to the hip, and is riveted while stretched (fig. 26).

SPINAL DEFORMITIES

Severe deformities of the trunk and pelvis cannot be satisfactorily fitted with the two-half-type back panel that is supplied in the Parapodium kit. Instead, a molded body jacket should be used.

With the patient sitting, a plaster-of-Paris wrap of the trunk and pelvis is made. Both sides of the wrap must be flat and parallel. A polyester-laminate lay-up can be molded on the plaster positive (fig. 28), or a vacuum-formed jacket can be made (fig. 29).
Lately we have been vacuum-forming jackets out of a transparent polycarbonate plastic, Lexan (TM), because the fit can be checked very carefully (4). The side mounting plate and front panel are removed from the panels that come with the kit and are transferred to the molded jacket (fig. 30).

When the patient is not able to sit up without leaning to one side, the lower edge of the body jacket can assist him to maintain sitting balance. The lower edge of the back panel touches the sitting surface, thereby providing a reaction point on each side of the thorax that helps the trunk to remain upright.

**OTHER MODIFICATIONS**

**SHOES**

When the lateral border of the shoe is touching the rib of the alignment unit, the lateral side of the sole of the shoe is sanded down until the shoes fit well into the footplate.

**HEEL AND TOE SPRING**

When the patient is rolling on the floor in the brace, occasionally the shoes will come out because the spring is not strong enough. In this event, the spring should be shortened, but not too short, so as to prevent the patient from clamping his shoes independently.

**ROTATION STRAPS AND WEDGES**

Uneven hip contractures can cause pelvic rotation, and a 2-in. webbing strap with Velcro can help. If, for instance, the left hip is contracted more than the right, the pelvis will rotate to the left. A padded strap that is riveted to the inside surface of the back panel on the right side and taken to a loop on the left side will tend to counteract the rotation. The padding over the iliac spines should be Plastazote glued to the inside of the strap.

To correct rotation of the trunk, the same principles are applied. In this case, the front panel strap is riveted to the inside support of the back panel.

**BACK PANEL**

Anterior-Posterior Instability

Patients who have difficulty sitting up without falling forward or backward can be assisted in two ways. The most common and effective method is to shape the back panel so that the lower lateral sides have substantial anterior extension and can then act...
as a 90-degree stop for the back panel. The second method is to supply them with 90-degree hip locks.

Protruding Coccyx

A cutout in the back panel, lined with Plastazote, relieves the pressure. In the case of one of our patients, before the cutout was made, a pressure reading of 35 psi was recorded.

Frank Panel

Instability of the Upper Thorax

With a high thoracic myelomeningocele, it is often difficult to prevent the head and shoulder from falling forward. A modified front panel with shoulder straps on the brace can help.

Lordosis

An enlarged version of the front panel with an extra set of lower straps might have a beneficial effect, but on the mobile curvature only.

Ileostomy

The front panel can be modified to accommodate an ileostomy conduit.

Handles

Handles are used to rotate the whole upright section; a 90-degree rotation locks and unlocks the brace. Note: The patient should never unlock the brace while standing; he should lie on the floor or sit in a chair first, then turn the handles to unlock the brace. If the brace unlocks inadvertently while the patient is walking, the direction of the knee axes should be checked (fig. 31). Also, the elastic strap of the back panel should be shortened.

As shown in figure 31, if a ruler is placed on the flat of the knee joint, there should be a 1/4-in. to 1/2-in. space between the ruler and the other joint body.

Ordering Kits

At the present time, the Parapodium is being manufactured in four children’s sizes:

- no. 603319, “super small,” shoe length 5 1/2 in. to 6 1/2 in.;
- no. 603320, “small,” shoe length 6 1/2 in. to 7 1/2 in.;
- no. 603321, “medium,” shoe length 7 1/2 in. to 8 1/2 in.;
- no. 603338, “large,” shoe length 8 1/2 in. to 9 1/2 in.

It is anticipated that various adult sizes of this device will be produced in the future.

Note: When ordering a Parapodium kit, obtain a pair of properly fitted lace-to-toe boots and measure the length of the sole in inches. This measurement determines the size of the kit. Once the shoe length (in inches) is given to the ordering department, the other parts can be selected.

Extra aluminum tubing (AL 2024T4) for lengthening the upright bars should be kept in stock:

- shin section ID $\frac{1}{2}$ in., OD 5/8 in.;
- thigh section ID .430 in., OD $\frac{1}{2}$ in.

Further information can be obtained from: Orthotic Research and Development Project, Spina Bifida Unit, Ontario Crippled Children’s Centre, 350 Rumsey Road, Toronto 350, Ontario, Canada.

Acknowledgments

My sincere thanks to Dr. N. C. Carroll, Dr. J. R. Corless, Dr. G. J. Lloyd, and Dr. C. A. McLaurin, and to all patients and staff who so generously helped to make this project possible.
